#### FDA U.S. FOOD & DRUG ADMINISTRATION

#### Bioequivalence Analysis of Lamotrigine Extended-Release (ER) Tablets based on an In Vitro-In Vivo Relationship (IVIVR) Using the Physiologically Based Pharmacokinetic (PBPK) Absorption Model

Edwin C.Y. Chow, Nan Zheng, Wen Qu, Dajun Sun, Hong Wen, Xinyuan Zhang, Wenlei Jiang, Liang Zhao Office of Research and Standards, Office of Generic Drugs, U.S. Food and Drug Administration

## **PURPOSE**

- Lamictal XR (lamotrigine ER tablets at strengths of 25, 50, 100, 200, 250, 300 mg) is a second generation anti-epilepsy drug (AED) taken once daily with or without food, indicated for the treatment of seizure control.
- As of June 2016, FDA has approved 8 generic copies of lamotrigine ER tablets which employ different controlled release mechanisms (see Figure below) from the reference listed drug (RLD) product owing to patent protection (DiffCORE).

- To demonstrate bioequivalence (BE) between generic lamotrigine ER tablets and the RLD, generic applicants are recommended to conduct single-dose, two-way, crossover BE studies in healthy subjects comparing the test products at 50 and 200 mg strengths with RLD, and other strengths may be eligible for waiver of in vivo studies if they meet all the criteria in product-specific guidance.
- This study aims to (1) based on formulation and dissolution analyses, evaluate the brand-to-generic BE for the strengths where in vivo BE studies were not conducted using a PBPK model as a prediction of the clinical significance of the dissolution differences (i.e. confirming a minimal risk of generic substitution at multiple strengths), and (2) select a generic product for a to-beconducted post-market PK BE study representing the worst-case scenario of generic switching.

## **METHOD**

- Generic A and B that are currently available on the market have been identified for simulation based on two criteria: (1) formulation proportionality and (2) in vitro dissolution of Test/RLD and Test/Test across all strengths.
- To develop an IVIVR, GastroPlus® (Simulations Plus Inc. Lancaster, CA) based on the ACAT (Advanced Compartmental Absorption and Transit) simulation model was used to perform PBPK modeling for the prediction of in vivo lamotrigine PK profiles. In vitro dissolution and in vivo PK data were collected from multiple Abbreviated New Drug Applications (ANDAs).
- Dissolution testing was conducted using a new dissolution method to simulate the pH transition of human gastrointestinal tract under fed conditions.
- The PBPK model was used to predict the in vivo PK profiles of the Generic A and B products at 50-200 mg administered with food using their dissolution profiles in support of a to-beconducted post-market PK BE study.

Assessing Strengths Waived for In Vivo BE Studies Generic A and B were identified based on formulation proportionality and comparative dissolution testing (Table 1).

**Table 1**. Formulation proportionality and comparative dissolution

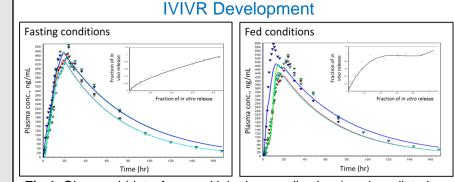

Fig 1: Observed (dots, from multiple drug applications) and predicted (lines, PBPK models) PK profiles of a single-dose 50-mg lamotrigine ER tablets under fasting and fed conditions. Inset: IVIV relationship

- The model adequately predicted the observed PK profiles of single-dose 50-mg lamotrigine in humans under fasting/fed conditions (Fig 1).
- An IVIVR between in vitro dissolution profiles and deconvoluted in vivo drug release was successfully established (insets of Fig 1).
- A new dissolution method (Table 2, fed) was proposed to simulate the fed condition. The Fasting dissolution method is compendial. The dissolution profiles of RLD and Generic A and B are shown in Fig
- Table 2. A new dissolution method simulating fasting and fed conditions Stage 1 Stage 2 2 hrs in 0.01 N HCI 20 hrs in pH 6.8 phosphate buffer with 2.25%SLS Fasting

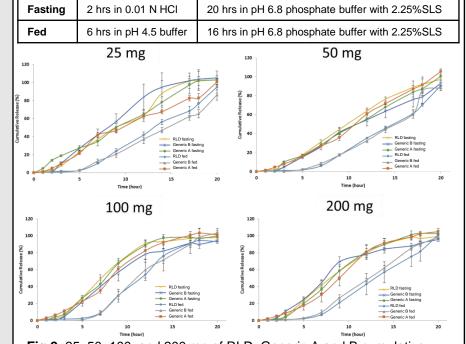

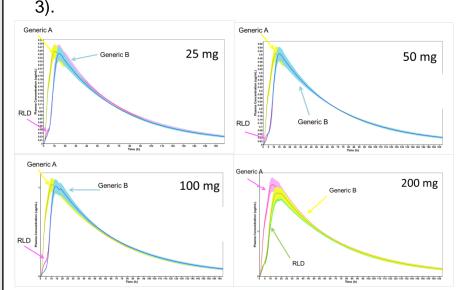

Fig 2. 25, 50, 100, and 200 mg of RLD, Generic A and B cumulative release using the new fasting and fed dissolution methods.

#### Passing Ratio (%) for Lamotrigine Virtual BE Trials

- multiple-dose (Table 5) studies.

Table 4. BE passing ratio (%) of Cmax, AUC <sub>inf</sub> and AUC <sub>0-t</sub> in single-
dose fed BE studies comparing 25-200 mg RLD vs Generic A
(upper panel) or B (lower panel) in randomly picked 1000 trials of N
(number of subjects) among 1000 simulations

25 mg	50 mg
100 mg	200 mg

#### Simulated BE Studies

The established PBPK model was used to simulate BE studies comparing RLD and Generic A or B after a single-dose administration of 25-200 mg lamotrigine ER tablets in 24 healthy subjects under fed conditions (Fig

Fig 3. PBPK modeling of single-dose fed BE studies comparing 25, 50, 100, and 200 mg of RLD vs. Generic A or B lamotrigine ER tablets. The

An inter-subject variability of 20% for volume of distribution (Vd) and 40% clearance was used for the single-dose BE simulation. The Test/RLD ratio with 90% confidence intervals (CI) of predicted PK metrics (i.e. Cmax and AUCt) for the generic lamotrigine ER tablets were entirely within the bioequivalence acceptance limits (i.e. 80%-125%) at 25-200 mg under

Although the F2 values for dissolution testing of Generic A at 100 and 250 mg vs. the BE strength (50 mg) are <50 (Table 1), the simulated PK results show BE between Generic A and the RLD (Table 3). 
 Table 3. Summary of PK metrics in simulated fed BE study (Fig 2)

In virtual clinical trials, 1000 times of (12-72 subjects) in a pool of 1000 simulations were randomly chosen. The BE passing ratio (%) (i.e. T/R ratio with 90%CI within 80-125%) of PK metrics was calculated based on 5% or 10% intra-subject CV in single-dose (Table 4) and

With a 5% intra-sub CV and N≥36, Generic A and B show a BE passing score >~47% when in a single-dose fed BE study at 25-200 mg (Generic A slightly lower than B), and  $>\sim$ 76% in a multiple-dose fed BE study.

# CONCLUSION

- Based on the single-dose PK simulations, generic lamotrigine ER tablets with a different release mechanism from the RLD appear to conform to the bioequivalence requirements of PK metrics (i.e. Cmax and AUCt) at strengths waived for in vivo BE studies.
- In the current study, virtual clinical trials based on PBPK modeling and simulation appear to be a powerful tool to predict PK profiles at strengths waived for in vivo BE studies and to confirm a minimal substitution risk of the generic drug products at 25-200 mg.
- RLD and Generic A (200 mg) were selected for the prospective clinical PK BE study to bracket the worst case scenario.
